

**2016, 1**

**Points 4, 1, 1, 1, 1, 2**

(a) (i)  $q = (110 \text{ g})(4.18 \text{ J g}^{-1} \text{ }^\circ\text{C}^{-1})(20.6 \text{ }^\circ\text{C}) = 9470 \text{ J} = 9.47 \text{ kJ}$

(ii)  $\Delta H_{\text{soln}} = \frac{9470 \text{ J}}{(10.0 \text{ g}/(6.94+35.45))} = -40.1 \text{ kJ mol}_{\text{rxn}}^{-1}$

(b)  $1s^2 2s^2 2p^6$

(c) The electronic configuration of  $\text{Li}^+$  is  $1s^2$ . A whole extra, quantum shell in the  $\text{Na}^+$  ion means that the ionic radius is significantly greater for Na.

(d) LiCl. Given lattice energy is governed by Coulomb's law, the smaller the value of  $r$  (the distance between the ions), and the larger the force of attraction between them. Since  $\text{Li}^+$  is smaller than  $\text{Na}^+$ ,  $\text{Li}^+$  and  $\text{Cl}^-$  can get closer together than  $\text{Na}^+$  and  $\text{Cl}^-$ . (I also like a comparison based upon the greater charge density of  $\text{Li}^+$  over  $\text{Na}^+$ , here).

(e)  $\text{Cl}^-$  on the left (the larger),  $\text{Li}^+$  on the right (the smaller).

(f)  $\text{H}_2\text{O}$  ( $\delta^-$  oxygen) to  $\text{Li}^+$ , and  $\text{H}_2\text{O}$  ( $\delta^+$  hydrogen) to  $\text{Cl}^-$ . Each can be described as dipole ( $\text{H}_2\text{O}$ ) to ion ( $\text{Li}^+$ ,  $\text{Cl}^-$ ) interactions.
